## THIS PAPER

Overview

- How does a worker's ability to adjust to economic shocks vary with the occupational intensity of routine tasks?
- Exposure to changing environment due to technological progress.
- Employment share of routine-intensive occupations has been falling over the past decades.
- Effect of job loss on future employment and wage earnings.
- To ensure an exogenous source of unemployment we use data from mass layoffs:
- Compare workers with identical careers but who work in occupations with different degrees of routine intensity.
- Use of a difference-in-differences approach.

## THIS PAPER

## Findings

- All workers affected by a mass layoff suffer from persistent negative effects on subsequent employment and earnings.
- These effects are considerably more pronounced for workers that were formerly employed in routine-intensive occupations.
- Negative earnings effects can be decomposed into similarly sized effects on employment duration and wages.
- Chance of re-employment in higher-quality jobs reduced.
- Transitions into other occupations or industries more likely.
- Adjustment more difficult in light of falling employment shares of routine-intensive occupations and devaluation of human capital.

## DATA AND VARIABLES <br> Mass layoff sample

- Identification of mass layoff workplaces based on the Establishment History Panel (BHP):
- Annual dataset of all establishments in Germany.
- Mass layoffs take place between 1980 and 2010.
- Match with the full employment biographies of affected workers:
- Taken from Integrated Employment Biographies (IEB).
- Only those with at least 3 years of tenure in the establishment.
- 12 quarters before and up to 24 quarters after the mass layoff.
- In total 9,365 establishments and 342,045 workers.

## DATA AND VARIABLES

Routine-intensity measure

- Occupations differ with respect to their contents and specifically to the extent that they contain routine components:
- Use of machines easier to implement in jobs characterised by routines.
- To obtain information on job contents we use data from an employee survey (Erwerbstätigenbefragung):
- Information on job characteristics at the worker level.
- Conducted by the Federal Institute for Vocational Education and Training (BIBB) and the Institute for Employment Research (IAB).
- Use data from the waves 1985, 1991, 1999.

## DATA AND VARIABLES

Routine-intensity measure

- Focus on two items in order to assess the extent of an occupation's routine intensity:
- Are the contents of your job minutely described by the employer?
- Does your job sequence repeat itself regularly?
- Possible answers: 'almost always', 'often', 'occasionally', 'rarely', 'hardly anytime'.
- The routine-intensity variable is defined as the fraction of workers reporting both items to be the case 'almost always'.

DESCRIPTIVE ANALYSIS The effects of mass layoffs

## DESCRIPTIVE ANALYSIS The effects of mass layoffs

## EMPIRICAL ANALYIS

Identification strategy and model

- Event-study approach:
- $y_{i t}=\alpha+\sum_{k \neq-1}\left[\beta_{k} R I_{i} \times I[t=k]+\delta_{k} I[t=k]\right]+\mu_{i}+\varphi_{t}+w_{i t}$
- Outcome variables:
- Quarterly earnings (in logs).
- Other outcomes: days in employment per quarter, average daily wage.
- Standard errors clustered at the occupational level.

## RESULTS

Baseline specification

RESULTS
Baseline specification

| RRI | Relative (k=1) | Relative (average) | Absolute (cum.) |
| :--- | ---: | ---: | ---: | ---: |
|  | Earnings |  |  |
| Percentage point | -0.07 | -0.03 | $-3,226.17$ |
| Standard deviation | -0.53 | -0.31 | $-29,797.25$ |
| Interdecile range | -0.84 | -0.60 | $-43,262.00$ |
|  | Employment |  |  |
| Percentage point | -0.04 | -0.02 | -24.79 |
| Standard deviation | -0.33 | -0.18 | -244.72 |
| Interdecile range | -0.63 | -0.39 | -443.35 |
|  | Daily earnings |  |  |
| Percentage point | -0.03 | -0.02 |  |
| Standard deviation | -0.29 | -0.16 |  |
| Interdecile range | -0.57 | -0.35 |  |

## RESULTS

Decomposition I

- Can we say anything about the source of these effects?
- Quarterly earnings are the product of days in employment and an average daily wage.
- Estimate corresponding models for these variables (in logs).
- The estimated coefficients add up to those from the earnings model.
- Both components appear equally important in magnitude:
- Employees from routine-intensive occupations are on average less likely to find employment and are employed in jobs paying lower wages.
- Differences in pre-treatment trends are more pronounced for earnings and wages than for employment duration.

## RESULTS

Decomposition I

## RESULTS

Decomposition I

## RESULTS <br> Decomposition II

- How do the careers of workers develop after the mass layoff?
- Does the initial degree of routine intensity affect the type of jobs that are subsequently found?
- Differentiate subsequent employment according to average wages as well as regional and occupational mobility.
- Initial employment in routine-intensive occupations decreases the chance of entering higher-paying jobs.
- It leads to higher occupational, but lower regional mobility.
- Moving into other occupations potentially associated with costs due to loss of human capital.

## CONCLUSION

- How does recovery from job loss vary with an occupation's routine intensity?
- Employment share of routine-intensive occupations declining.
- Use of mass layoffs to identify exogenous shock.
- Persistent negative effects in terms of subsequent employment duration and earnings.
- Substantially larger for individuals formerly employed in routineintensive occupations.
- Adjustment to shocks more difficult for this group of individuals.
- This form of human capital has become less valuable, potentially due to technological progress.

## EMPIRICAL ANALYIS <br> Identification strategy and model

- Potential-outcomes framework:
- Treatment: mass layoff.
- Treatment measure: routine intensity in the quarter before the layoff.
- The expected marginal effect of the treatment measure on the outcome is:
- $E\left[d y_{t}{ }^{1} \mid t \geq z\right]=E\left[\beta_{t} d T \mid t \geq z\right]$
- $\beta_{\mathrm{t}}$ is a quarter-specific parameter.
- Problem of identification:
- What would have been the marginal effect of the treatment measure in the absence of treatment?
- $E\left[d y_{t}{ }^{0} \mid t \geq z\right]$ is not observable.

## EMPIRICAL ANALYIS <br> Identification strategy and model

- The marginal effect of the treatment measure can be estimated for the pre-treatment period (given that treatment is not active):
- $E\left[d y_{t}{ }^{0} \mid t<z\right]=E\left[\beta_{t} d T \mid t<z\right]$
- Assume that the marginal treatment effect interacts linearly with time.
- Regress the estimated year effects on a linear time trend:
- $\hat{\beta}_{t}=\gamma_{0}+\gamma_{1} t+v_{t}$
- The counterfactual marginal effect of the treatment measure is:
- $E\left[d y_{t}{ }^{0} \mid t \geq z\right]=E\left[\gamma_{0}+\gamma_{1} t \mid t \geq z\right] d T$
- Accordingly, the treatment effect is given by:
- $E\left[d y_{t}{ }^{1} \mid t \geq z\right]-E\left[d y_{t}{ }^{0} \mid t \geq z\right]=E\left[\beta_{t}-\gamma_{0}-\gamma_{1} t\right] d T$
