Automation and Job Polarization: On the Decline of Middling Occupations in Europe

Vahagn Jerbashian

Universitat de Barcelona and CERGE-EI

IBS Jobs Conference (December 6-7, 2017)

#### Motivation

- ▶ In labor markets, a prominent and relatively recent phenomenon is
  - Increasing shares of employment (as well as wages) in low and high wage occupations

◆□▶ ◆□▶ ◆□▶ ◆□▶ □□ ��

- Falling share of employment in medium wage occupations
- Goos and Manning (2007) call this "Job Polarization"

## Motivation

- Information technologies (IT) are thought to be one of the major causes of these trends
  - IT substitute for routine tasks, which are readily automatable and are usually performed by middle wage occupations, such as office clerks
  - IT complement nonroutine cognitive tasks, which require abstract reasoning and are usually performed by high wage occupations, such as managers
- The raise of employment in highly paid occupations increases the demand for nonroutine manual tasks, which are usually performed by low wage occupations, such as personal services

#### Research

- I investigate the effect of the fall in IT prices on industries' demand for high, middle and low wage occupations
  - I use a DiD framework in the spirit of Rajan and Zingales (1998)

▲□▶▲□▶▲≡▶▲≡▶ Ξ|= めぬ⊙

#### Research

- I ask whether the fall in IT prices has affected the demand for high, middle and low wage occupations more in industries which depend more on IT compared to industries which depend less
  - I use industry- and country-level data from 10 Western European countries and 1993-2007 period

◆□▶ ◆□▶ ◆□▶ ◆□▶ □□ ��

## Results

- The share of employment in middling occupations has declined and the share of employment in high wage occupations has increased with the fall in IT prices
- I find no systematic evidence that the fall in IT prices affects the share of employment in the lowest paid occupations
- Similar results hold within gender and age groups
  - These findings provide a support for the hypothesis put forward for explaining job polarization
  - They are broadly in line with and complement the results of Autor et al. (2003); Autor and Dorn (2013); Goos et al. (2014), and Michaels et al. (2014), amongst others

## Results

- The fall in IT prices has increased (reduced) the share of employment in high (medium) wage occupations among females more than among males
- It has increased (reduced) the share of employment in high (medium) wage occupations among old workers less than among young and medium-age workers
  - These results are robust to a wide range of specification checks and alternative identifying assumptions

An explanation is that efficiency (advantage) in performing tasks varies with age and gender

- Men are more endowed with hard motor skills (brawn) than women, which are important in many medium wage occupations
- Older employees can be more efficient in routine occupations since workers accumulate routine skills as they age (Autor and Dorn, 2009)

## Related Literature

- Autor et al. (2006); Goos and Manning (2007); Autor et al. (2008); Goos et al. (2009); Acemoglu and Autor (2011); Autor and Dorn (2013); Goos et al. (2014): Polarization in the US and EU
- Autor and Dorn (2013); Michaels et al. (2014): The effects of IT in commuting zones in the US and on high, medium and low educated workers
- Cortes et al. (2016); Cerina et al. (2016): Differences in the trends of polarization across genders in the US

#### Theoretical Background

The producers use abstract and routine task inputs,  $T_A$  and  $T_R$ , and IT, to produce homogenous goods, Y

$$Y = \left(\alpha_{IT} I T^{\frac{\varepsilon-1}{\varepsilon}} + \alpha_{T_R} T_R^{\frac{\varepsilon-1}{\varepsilon}}\right)^{\frac{\varepsilon}{\varepsilon-1}\alpha} T_A^{1-\alpha},$$

where  $\alpha_{IT} > 0$ ,  $\alpha_{T_R} > 0$ ,  $\alpha \in (0, 1)$ , and  $\varepsilon > 1$ .

- $\alpha_{IT}$  measures the relative importance of IT and higher  $\alpha_{IT}$  implies higher share of compensation for IT
- Since ε > 1, information technologies are more complementary to abstract tasks than to routine tasks.

#### Theoretical Background

Let  $p_z$  be the price of input z. It can be shown that  $\partial \ln IT / \partial p_{IT} < 0$ ,

$$\frac{\partial T_A/T_R}{\partial p_{IT}} = \frac{\varepsilon - 1}{\varepsilon} \frac{\partial \ln IT}{\partial p_{IT}} \frac{1 - \alpha}{\alpha} \frac{p_{T_R}}{p_{T_A}} \frac{\alpha_{IT} IT^{\frac{\varepsilon - 1}{\varepsilon}}}{\alpha_{T_R} T_R^{\frac{\varepsilon - 1}{\varepsilon}}} < 0$$

and

$$\frac{\partial}{\partial \alpha_{IT}} \left| \frac{\partial T_A/T_R}{\partial p_{IT}} \right| = \frac{1}{\alpha_{IT}} \left| \frac{\partial T_A/T_R}{\partial p_{IT}} \right| > 0$$

This implies that the decline of  $p_{IT}$  increases  $T_A$  more than the demand for  $T_R$  and this effect is stronger in industries with a larger  $\alpha_{IT}$ 

▲□▶▲□▶▲≡▶▲≡▶ Ξ|= めぬ⊙

I incorporate the demand side into a simple Ricardian model for within age and gender groups inference

Workers are endowed with labor hours L which need to be converted into abstract and routine tasks

- The conversion function of task  $k = T_A$ ,  $T_R$  is  $\alpha_{L,k} (u_k L)^{\gamma}$ , where
  - $\alpha_{L,k} > 0$  and  $\gamma \in (0,1)$
  - $u_k$  is the share of labor hours converted to task k

#### Theoretical Background

This setup implies that the supply of abstract tasks relative to the supply of routine tasks is given by

$$\frac{p_{T_A}}{p_{T_R}} = \frac{\alpha_{L,T_R}}{\alpha_{L,T_A}} \frac{(u_{T_R}L)^{\gamma-1}}{(u_{T_A}L)^{\gamma-1}},$$

and the share of employment in abstract tasks is given by

$$\frac{u_{T_A}}{1-u_{T_A}} = \frac{1-\alpha}{\alpha} \left( \frac{\alpha_{IT} I T^{\frac{\varepsilon-1}{\varepsilon}}}{\alpha_{T_R} \{ \alpha_{L,T_R} [(1-u_{T_A}) L]^{\gamma} \}^{\frac{\varepsilon-1}{\varepsilon}}} + 1 \right)$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三回■ のへの

#### Theoretical Background

It is straightforward to show that

- A fall in *p<sub>IT</sub>* increases the share of employment in abstract tasks *u<sub>T<sub>A</sub></sub>* and it has a stronger effect in industries which have a higher *α<sub>IT</sub>*
- This differential effect of the fall in p<sub>IT</sub> on u<sub>T<sub>A</sub></sub> (and u<sub>T<sub>R</sub></sub>) is weaker in groups which have a higher α<sub>T<sub>R</sub></sub>:

$$\frac{\partial}{\partial \alpha_{T_R}} \frac{\partial}{\partial \alpha_{IT}} \left| \frac{\partial u_{T_A}}{\partial p_{IT}} \right| < 0$$

## **Empirical Specification**

For each occupation group, I estimate

Employment Share<sub>c,i,t</sub> = 
$$\beta \left[ \text{Industry i's Dependence on IT}_i \times (1/\text{IT Price})_{c,t} \right]$$
  
+  $\sum_{c} \sum_{i} \zeta_{c,i} + \sum_{c} \sum_{t} \xi_{c,t} + \eta_{c,i,t},$ 

where

- Employment Share<sub>c,i,t</sub> is the share of employment in one of the occupation groups, country c, industry i, and year t
- ζ and ξ are country-industry and country-year fixed effects, and η is an error term

## Data

- ► The sample consists of 10 Western European countries
- On average, for each country I have 14 years of observations from the period of 1993-2007
- For each country and year, I obtain from the EU LFS database the number of employed individuals in each
  - occupation (2 digit ISCO-88) I group occupations into high, medium and low wage (Goos et al., 2014)
  - industry (1 digit NACE Rev. 1)
  - gender
  - age group (in-between 17-32: young; in-between 32 and 47: medium-age; in-between 47-62: old)

◆□▶ ◆□▶ ◆□▶ ◆□▶ □□ ��

and their usual weekly employment hours

### **IT** Measures

- IT Price: The price of investments in information technologies relative to the price of value added in sample countries
  - I use the inverse of this measure in the estimations
  - β is expected to be positive for high wage occupations and negative for medium wage occupations
- IT Dependence: The share of IT capital compensation in industrial value added in the US industries, averaged over the sample period

### The Interpretation of $\beta$

## Conclusions

I offer international evidence corroborating one of the main hypotheses for job polarization

- The share of employment in high (medium) wage occupations has increased with the fall of IT prices
  - Technological heterogeneity across industries creates important differences in terms of response of employment shares to changes in IT prices

- The effects of IT on employment shares are stronger
  - for women than for men
  - for young and medium-age than for old
